1. The mapping class group of a surface $\text{Mod}(\mathcal{S})$

The **mapping class group** of a surface \mathcal{S} is the group

$$\text{Mod}(\mathcal{S}) = \text{Homeo}^+(\mathcal{S}, \partial\mathcal{S}) / \sim,$$

where \sim denotes smooth isotopy relative to the boundary.

A **mapping class** in $\text{Mod}(\mathcal{S})$:

- ▶ is an isotopy class of orientation-preserving homeomorphism of \mathcal{S} ,
- ▶ preserves the marked points of \mathcal{S} setwise,
- ▶ preserves $\partial\mathcal{S}$ pointwise.

2. Dehn twists in $\text{Mod}(\mathcal{S})$

Parameterise a regular annular neighbourhood \mathbf{A} of a simple closed curve \mathbf{c} on a surface \mathcal{S} by $\mathbf{A} = re^{i\theta}$. The **twist map about \mathbf{c}** is the homeomorphism $(r, \theta) \mapsto (r, \theta + 2\pi r)$.

A **Dehn twist about \mathbf{c}** , denoted $T_{\mathbf{c}}$, is the homeomorphism induced by performing the twist map about \mathbf{c} and extending by the identity on the rest of \mathcal{S} .

Figure: A Dehn twist $T_{\mathbf{c}}$.

The Dehn twist $T_{\mathbf{c}}$ is an important mapping class in $\text{Mod}(\mathcal{S})$:

- ▶ $T_{\mathbf{c}}$ is orientation preserving,
- ▶ $\partial\mathbf{A}$ is fixed pointwise under $T_{\mathbf{c}}$, so $\partial\mathcal{S}$ is fixed pointwise,
- ▶ marked points in \mathcal{S} are preserved setwise,
- ▶ $T_{\mathbf{c}}$ is well-defined on the isotopy class of \mathbf{c} .

Figure: The mapping class group of a genus g surface $\text{Mod}(\mathcal{S}_g)$ is generated by $2g + 1$ Dehn twists, known as the Humphries generators.

3. Intersection numbers

Consider two oriented simple closed curves \mathbf{a} and \mathbf{b} on an oriented surface \mathcal{S}_g .

▶ **Geometric intersection number:**

$$i(\mathbf{a}, \mathbf{b}) = \min\{|\mathbf{a} \cap \mathbf{b}| : \mathbf{a} \in [\mathbf{a}], \mathbf{b} \in [\mathbf{b}]\}.$$

▶ **Algebraic intersection number:**

$$\hat{i}(\mathbf{a}, \mathbf{b}) = \sum_{p \in \mathbf{a} \cap \mathbf{b}} \text{sgn}(p),$$

where $\text{sgn}(p) = 1$ if the orientation of the intersection point p agrees with the orientation of \mathcal{S}_g and $\text{sgn}(p) = -1$ otherwise.

Figure: A pair of curves, \mathbf{a} and \mathbf{b} , with $i(\mathbf{a}, \mathbf{b}) = 2$ and $\hat{i}(\mathbf{a}, \mathbf{b}) = 0$.

The algebraic intersection number is a **symplectic form** on the first homology group of a genus g surface.

4. The Torelli group $\mathcal{I}(\mathcal{S}_g)$

The **Torelli group $\mathcal{I}(\mathcal{S}_g)$** is the kernel of the symplectic representation ρ , expressed in the exact sequence:

$$1 \longrightarrow \mathcal{I}(\mathcal{S}_g) \longrightarrow \text{Mod}(\mathcal{S}_g) \xrightarrow{\rho} \text{Sp}_{2g}(\mathbb{Z}) \longrightarrow 1$$

where $\text{Sp}_{2g}(\mathbb{Z})$ denotes the integral symplectic group.

The symplectic representation ρ is generally not faithful - so it makes sense for us to talk about the Torelli group.

The action of a Dehn twist on homology is described by the formula:

$$\rho(T_{\mathbf{b}}^k)([\mathbf{a}]) = [\mathbf{a}] + k \cdot \hat{i}(\mathbf{a}, \mathbf{b})[\mathbf{b}].$$

Figure: $T_{\mathbf{b}}^3(\mathbf{a})$ represents the homology class obtained by applying $T_{\mathbf{b}}^3$ to $[\mathbf{a}]$.

Mapping classes in the Torelli group act trivially on homology: If $\mathbf{x} \in \mathcal{I}(\mathcal{S}_g)$ then $\rho(\mathbf{x})([\mathbf{a}]) = [\mathbf{a}]$ for all $[\mathbf{a}] \in H_1(\mathcal{S}_g, \mathbb{Z})$.

5. Mapping classes in the Torelli group $\mathcal{I}(\mathcal{S}_g)$

Let \mathbf{a} be a separating simple closed curve on \mathcal{S}_g .

▶ **Separating twists $T_{\mathbf{a}}$** are in $\mathcal{I}(\mathcal{S}_g)$.

Let \mathbf{b} and \mathbf{c} be non-separating oriented simple closed curves on \mathcal{S}_g .

▶ **Bounding pair maps $T_{\mathbf{b}}T_{\mathbf{c}}^{-1}$** are in $\mathcal{I}(\mathcal{S}_g)$, where $[\mathbf{b}] = [\mathbf{c}]$, $\hat{i}(\mathbf{b}, \mathbf{c}) = 0$ and $i(\mathbf{b}, \mathbf{c}) = 0$.

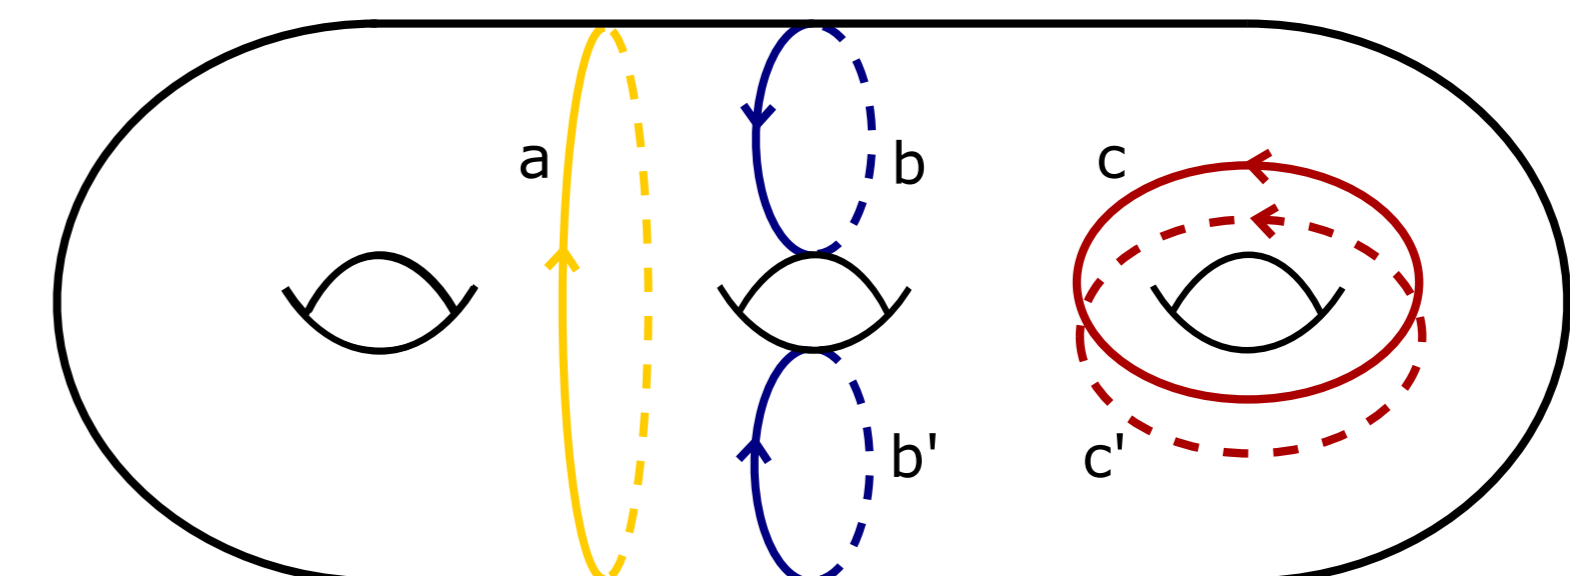

Figure: The curve \mathbf{a} defines a separating curve, while pairs \mathbf{b} and \mathbf{b}' , \mathbf{c} and \mathbf{c}' are examples of bounding pairs.

▶ **Fake bounding pair maps $T_{\mathbf{b}}T_{\mathbf{c}}^{-1}$** are in $\mathcal{I}(\mathcal{S}_g)$, where $[\mathbf{b}] = [\mathbf{c}]$, $\hat{i}(\mathbf{b}, \mathbf{c}) = 0$ and $i(\mathbf{b}, \mathbf{c}) \neq 0$.

▶ **Simply intersecting pair maps $[T_{\mathbf{b}}, T_{\mathbf{c}}] = T_{\mathbf{b}}T_{\mathbf{c}}^{-1}T_{\mathbf{b}}$** are in $\mathcal{I}(\mathcal{S}_g)$, where $\hat{i}(\mathbf{b}, \mathbf{c}) = 0$ and $i(\mathbf{b}, \mathbf{c}) = 2$.

Figure: The pair \mathbf{d} and \mathbf{d}' define a special case of a fake bounding pair: a simply intersecting pair. Notice $[\mathbf{d}] \neq [\mathbf{d}']$, but that $[\mathbf{d}] = [T_{\mathbf{d}'}(\mathbf{d})]$.

6. Remarks on the Torelli group

- ▶ The Torelli group $\mathcal{I}(\mathcal{S}_1)$ is trivial.
- ▶ The Torelli group can be generated by separating twists and bounding pair maps.
- ▶ The Torelli group plays a role in the study of other groups, such as in the representation theory of the braid group.
